How do we use a computer to simulate a chance process?

Case Study

Chevalier de Mere

- ► Antoine Gombaud (1607 1684)
- ▶ Nom de plume "Chevalier de Mere"
- French writer and gambler, but not a nobleman
- Amateur mathematician

De Mere's games

Game 1

- ► One die
- ► Four rolls
- ▶ Win: at least one 6

De Mere's games

Game 1

- ► One die
- ► Four rolls
- ▶ Win: at least one 6

Game 2

- ► Two dice
- ▶ 24 rolls
- ▶ Win: at least one double 6

De Mere's games

Game 1

- ▶ One die
- ► Four rolls
- Win: at least one 6

Game 2

- Two dice
- ▶ 24 rolls
- Win: at least one double 6

De Mere was making money with game 1, but losing money with game 2. He turned to Blaise Pascal for help.

De Mere's faulty reasoning

Game 1

- ▶ The chance of getting a six in one roll of a die is $\frac{1}{6}$.
- ▶ In four rolls of a die, the chance of getting one six would be $\frac{4}{6} = \frac{2}{3}$.

De Mere's faulty reasoning

Game 2

- ► The chance of getting a double six in rolling a pair of dice is $\frac{1}{36}$.
- ▶ In 24 rolls of a pair of dice, the chance of getting one double six would be $\frac{24}{36} = \frac{2}{3}$.

Pascal and Fermat

- De Mere turned into Blaise Pascal
- Pascal consulted with Pierre de Fermat
- Beginning of Pascal's and Fermat's famous correspondence (1650's)
- Origin of combinatorial probability

Blaise Pascal (1623 - 1662) French mathematician

Pierre de Fermat (1601 - 1665) French lawyer and amateur mathematician

Letter from Pascal to Fermat

"If one undertakes to throw a six with one die, the advatange of undertaking it in 4 throws is as 671 to 625. If one undertakes to throw a double-six with two dice, there is a disadvantage of undertaking it in 24 throws. And nevertheless 24 is to 36 (which is the number of faces of two dice) as 4 to 6 (which is the number of faces of one die)."

Probability of no six in four rolls:

$$\frac{5}{6} \times \frac{5}{6} \times \frac{5}{6} \times \frac{5}{6} = \frac{625}{1296} = 0.482253$$

Probability of no six in four rolls:

$$\frac{5}{6} \times \frac{5}{6} \times \frac{5}{6} \times \frac{5}{6} = \frac{625}{1296} = 0.482253$$

P(at least one six) = 1 - Probability of no six in four rolls:

$$1 - \frac{625}{1296} = \frac{671}{1296} = 0.517747$$

Probability of no double six in 24 rolls:

$$P(\text{no double six in 24 rolls}) = \left(\frac{35}{36}\right)^{24} = 0.5086$$

Probability of no double six in 24 rolls:

$$P(\text{no double six in 24 rolls}) = \left(\frac{35}{36}\right)^{24} = 0.5086$$

P(at least one double six in 24 rolls) =

$$1 - 0.5086 = 0.4914$$

Using a computer to simulate a chance process

Some Questions

- ► Rather than solve the problem analytically, we can simulate 4 rolls of a die and count the number of 6's
- ▶ If we simulate rolling 4 dice many times, then the proportion of times we get 0, 1, 2, 3, or 4 sixes should be close to the chance of that many sixes on any 4 rolls

Some Questions

- ▶ What is the chance of getting one 6 when rolling a die?
- ▶ What is the chance of getting one 6 when rolling two dice?
- What is the chance of getting at least one 6 when rolling 4 dice?

What are the steps?

- ► Simulate rolling one die
- Simulate rolling a pair of dice
- Simulate rolling four dice
- Count the number of sixes

Simulating one die

- ▶ Let's start with one die
- ▶ What features?
- ► How to create a die object?

One die

```
die <- 1:6
die
## [1] 1 2 3 4 5 6</pre>
```

Your turn

Which option would produce an invalid die:

```
# A
die <- 1L:6L
# B
die \leftarrow seq(from = 1, to = 6)
# C
die \leftarrow c(1, 2, 3, 4, 5, 6)
# D
die \leftarrow seq(from = 1, to = 6, by = 6)
# E
die <- seq_len(6)
```

How to simulate the roll of a die?

sample()

Very useful function for selecting from a discrete set (vector) of possibilities.

sample() arguments

- X
- ▶ size
- ▶ replace
- ▶ prob

Roll a die

```
# use of sample() to simulate the roll of a die
sample(die, size = 1)
## [1] 2
```

Roll a die

```
# use of sample() to simulate the roll of a die
sample(die, size = 1)
## [1] 2
```

```
sample(die, size = 1)
## [1] 2
sample(die, size = 1)
## [1] 5
sample(die, size = 1)
## [1] 6
```

Function: Roll one die

Write a function to make it more convenient

```
# function
rolldie <- function() {
}</pre>
```

Function: Roll one die

Write a function to make it more convenient

```
# function
rolldie <- function() {
  die <- 1:6
   sample(die, size = 1)
}</pre>
```

Function: Roll one die

Write a function to make it more convenient

```
# function
rolldie <- function() {
  die <- 1:6
  sample(die, size = 1)
}</pre>
```

```
rolldie()
## [1] 2
```

Let's simulate 10 rolls of a die

```
# roll 10 times
for (i in 1:10) {
  rolldie()
}
```

Let's simulate 10 rolls of a die

```
# roll 10 times
for (i in 1:10) {
   rolldie()
}
```

What's wrong?

Why nothing is shown on screen?

```
# roll 10 times
for (i in 1:10) {
 print(rolldie())
## [1] 2
## [1] 3
## [1] 4
## [1] 6
## [1] 2
## [1] 6
## [1] 6
## [1] 4
## [1] 4
## [1] 1
```

```
# roll until first 5
repeat {
 rol <- rolldie()</pre>
 print(rol)
  if (rol == 5) break
## [1] 4
## [1] 2
## [1] 6
## [1] 4
## [1] 3
## [1] 6
## [1] 5
```

Rolling one die

```
# roll until first 5
rol <- 1
while (rol != 5) {
 rol <- rolldie()</pre>
 print(rol)
## [1] 4
## [1] 2
## [1] 6
## [1] 4
## [1] 3
## [1] 6
## [1] 5
```

Rolling one die

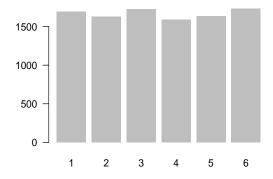

```
# roll 10,000 times
results <- numeric(10000)

for (i in 1:10000) {
   results[i] <- rolldie()
}</pre>
```

Rolling one die

```
# frequencies
table(results)
## results
  1 2 3 4 5 6
## 1692 1631 1724 1586 1633 1734
# relative frequencies
table(results) / 10000
## results
##
  1 2 3 4
## 0.1692 0.1631 0.1724 0.1586 0.1633 0.1734
```

Distribution of results

How to simulate a loaded die?

Loaded Die

Changing argument prob to create a loaded die

```
probs <- c(1/21, 2/21,3/21, 4/21, 5/21, 6/21)
# function
loaded <- function() {
   die <- 1:6
   sample(die, size = 1, prob = probs)
}</pre>
```

Loaded Die

Changing argument prob to create a loaded die

```
probs <- c(1/21, 2/21,3/21, 4/21, 5/21, 6/21)

# function
loaded <- function() {
   die <- 1:6
   sample(die, size = 1, prob = probs)
}</pre>
```

```
loaded()
## [1] 6
```

Rolling a loaded die

```
# roll 10 times
for (i in 1:10) {
 print(loaded())
## [1] 6
## [1] 5
## [1] 4
## [1] 2
## [1] 6
## [1] 2
## [1] 2
## [1] 4
## [1] 4
## [1] 6
```

Rolling a loaded die

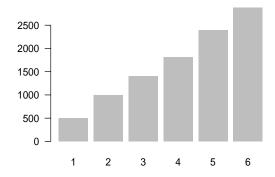

```
# roll 10,000 times
results <- numeric(10000)

for (i in 1:10000) {
   results[i] <- loaded()
}</pre>
```

Rolling a lodade die

```
# frequencies
table(results)
## results
  1 2 3 4 5 6
##
## 505 1000 1405 1817 2391 2882
# relative frequencies
table(results) / 10000
## results
##
  1 2 3 4
## 0.0505 0.1000 0.1405 0.1817 0.2391 0.2882
```

Loaded Distribution

Simulating rolling a pair of dice

```
# 1st die
sample(die, size = 1)
## [1] 1
# 2nd die
sample(die, size = 1)
## [1] 5
```

Function

```
# pair of dice function
roll2 <- function() {</pre>
```

```
# pair of dice function
roll2 <- function() {
    die <- 1:6
    rol1 <- sample(die, size = 1)
    rol2 <- sample(die, size = 1)
    c(rol1, rol2)
}</pre>
```

Various rolls

```
roll2()
## [1] 5 1
rol12()
## [1] 1 1
roll2()
## [1] 6 6
```

Function

```
# pair of dice function
roll2 <- function() {
    die <- 1:6
    rol1 <- sample(die, size = 1)
    rol2 <- sample(die, size = 1) # repeated command!
    c(rol1, rol2)
}</pre>
```

```
die <- 1:6
# avoid repetition with one call of 'sample()'
sample(die, size = 2)
## [1] 6 1</pre>
```

```
for (i in 1:15) {
  print(sample(die, size = 2))
## [1] 1 3
## [1] 1 4
## [1] 5 4
  [1] 4 3
## [1] 3 1
## [1] 2 6
## [1] 4 6
## [1] 3 4
## [1] 4 6
## [1] 6 3
## [1] 2 5
## [1] 2 5
## [1] 2 3
## [1] 3 2
## [1] 2 5
# Can you spot a problem?
```

```
die <- 1:6
# sample with replacement
sample(die, size = 2, replace = TRUE)
## [1] 4 1</pre>
```

```
for (i in 1:15) {
  print(sample(die, size = 2, replace = TRUE))
## [1] 6 6
## [1] 6 5
   [1] 5 4
## [1] 3 6
## [1] 1 2
   [1] 1 5
## [1] 1 2
## [1] 3 1
## [1] 6 1
  [1] 1 2
## [1] 1 6
   [1] 3 2
## [1] 3 1
## [1] 2 2
## [1] 1 1
```

```
# rewrite roll2()
roll2 <- function() {
  die <- 1:6
   sample(die, size = 2, replace = TRUE)
}</pre>
```

```
# rewrite roll2()
roll2 <- function() {
  die <- 1:6
   sample(die, size = 2, replace = TRUE)
}</pre>
```

```
roll2()
## [1] 5 4
```

Rolling a die any number of times

Rolling several dice

More general function to roll a die any number of times

```
roll <- function(times = 1) {
  die <- 1:6
  sample(die, size = times, replace = TRUE)
}</pre>
```

Rolling several dice

More general function to roll a die any number of times

```
roll <- function(times = 1) {
  die <- 1:6
  sample(die, size = times, replace = TRUE)
}</pre>
```

```
roll()
## [1] 4
```

Rolling several dice

```
# default (one roll)
roll()
## [1] 4
# two rolls
roll(2)
## [1] 1 5
# 4 rolls
roll(4)
## [1] 6 4 6 5
```

Game 1

- ► One die
- ► Four rolls
- ▶ Win: at least one 6

```
# play 100 times
results <- matrix(0, nrow = 100, ncol = 4)
for (i in 1:100) {
 results[i, ] <- roll(times = 4)
head(results)
## [,1] [,2] [,3] [,4]
## [1,] 2 5 4 2
## [2,] 6 6 1 6
## [3,] 3 4 4 2
## [4,] 5 2 3 6
## [5,] 6 2 3 1
## [6,] 4 3 6
```

```
counts <- 0
for (i in 1:100) {
  if (any(results[i, ] == 6))
    counts <- counts + 1
# proportion of wins
counts / 100
## [1] 0.56
```

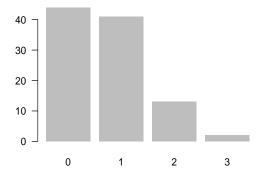

```
sixes <- apply(results, 1, function(x) sum(x == 6))
table(sixes)

## sixes
## 0 1 2 3
## 44 41 13 2</pre>
```

```
sixes <- apply(results, 1, function(x) sum(x == 6))
table(sixes)

## sixes
## 0 1 2 3
## 44 41 13 2</pre>
```

```
# rolls with at least one six
sum(table(sixes)[-1])
## [1] 56
```

Considerations

- ▶ How would you make the code more flexible?
- ▶ What type of "parameters"?
- Avoid Repetition

```
games <- 10000
results <- matrix(0, nrow = games, ncol = 4)
for (i in 1:games) {
  results[i, ] <- roll(times = 4)
counts <- 0
for (i in 1:games) {
  if (any(results[i, ] == 6))
    counts <- counts + 1
counts / games # proportion of wins
## [1] 0.5204
```

```
sixes <- apply(results, 1, function(x) sum(x == 6))

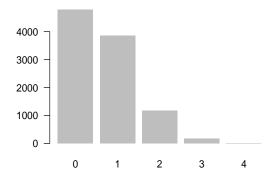

table(sixes)

## sixes
## 0 1 2 3 4
## 4796 3858 1171 166 9</pre>
```

```
sixes <- apply(results, 1, function(x) sum(x == 6))
table(sixes)

## sixes
## 0 1 2 3 4
## 4796 3858 1171 166 9</pre>
```

```
# rolls with at least one six
sum(table(sixes)[-1])
## [1] 5204
```

Game 2

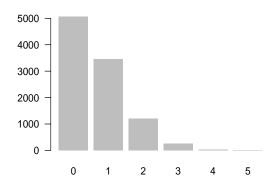

- ► Two dice
- ▶ 24 rolls
- ▶ Win: at least one double 6

```
roll2 <- function(times = 1) {</pre>
 dice2 <- unlist(lapply(1:6, function(x) x + 1:6))
 sample(dice2, size = times, replace = TRUE)
rol12()
## [1] 10
roll2(24)
       8 4 4 3 8 6 7 6 9 9 5 4 5 7 3 11 9 11
##
```

Game 2

- ▶ It's better if we sum the points of rolling two dice
- Possible outcomes: $\{2, 3, 4, ..., 10, 11, 12\}$
- ▶ Double six is equivalent to 12 points

```
games <- 10000
results <- matrix(0, nrow = games, ncol = 24)
for (i in 1:games) {
 results[i, ] <- roll2(24)
doublesix <- apply(results, 1, function(x) sum(x == 12))</pre>
sum(table(doublesix)[-1])
## [1] 4930
```

```
counts <- 0
for (i in 1:games) {
  if (any(results[i, ] == 12))
    counts <- counts + 1
}

counts / games # proportion of wins
## [1] 0.493</pre>
```
